The Biology of Chameleons - WordPress.com

Chameleons present black, red and yellow chromatophores, which they can contract and expand voluntarily. Also, in a study conducted with panther chameleons (*Furcifer pardalis*), it's been proved that they also present two layers of guanine nanocrystal-bearing cells, called iridiophores, which reflect light. Then a chameleon's green coloration is acquired by the blue light reflected by the iridiophores that goes through the outer yellow chromatophores.

Cuttlefish are known as the chameleons of the sea – they can blend in seamlessly with their surroundings, even if they've never seen them before. Besides being the deep sea masters of disguise, they're also known for being producers of an ink, used to protect them from predators, in exactly the same way as octopuses and squid do.

Chameleons have very unique tongues specialized for capturing their prey. An extensive study

done in 2000 revealed the complexities of how the chameleon tongue works. The capture of prey was often attributed only to adhesion to the tongue pad but now scientists believe the speed and form of the tongue also creates a suction device.
